Running docker-compose up -d starts the containers in the background and leaves them running. If there are existing containers for a service, and the service's configuration or image was changed after the container's creation, docker-compose up picks up the changes by stopping and recreating the containers (preserving mounted volumes).

The docker run command first creates a writeable container layer over the specified image, and then starts it using the specified command. That is, docker run is equivalent to the API /containers/create then /containers/ (id)/start. A stopped container can be restarted with all its previous changes intact using docker start.

Docker Compose has an `-f` flag where you can pass in the location of the `docker-compose.yml` file (or a custom file if you happen to name it something different). That means you could run: `docker-compose -f /tmp/myproject/docker-compose.yml up -d` from anywhere on your file system and things will work. I use this a lot in my scripts.
